Table of Contents

1. Basic Setup

2. Process

1. Basic Setup

This process is necessary to bring your changes to the main branch. We split in branches to make sure conflicts are resolved and unwanted changes are removed.

You have changes on your local branch. These are reviewed by the manager and need to be merged into main.

Make sure you follow the instructions (**FF OI 05**) to install the build and set up yourself as developer with access to the repository on github. I am using Github Desktop for local front end management.

2. Process

1. **Merge main into your branch; except for your intentional changes.**

This will make sure, nothing is overwritten with older variants or dirty edits from your branch. A dirty edit is an unintended change; even if it does not effectively change logic, it is change for the build, and per se unwanted. Older Variant means, your change is not up to date with other branches or main, and would overwrite other, more recent and higher prioritized changes, effectively removing work effort and progress.

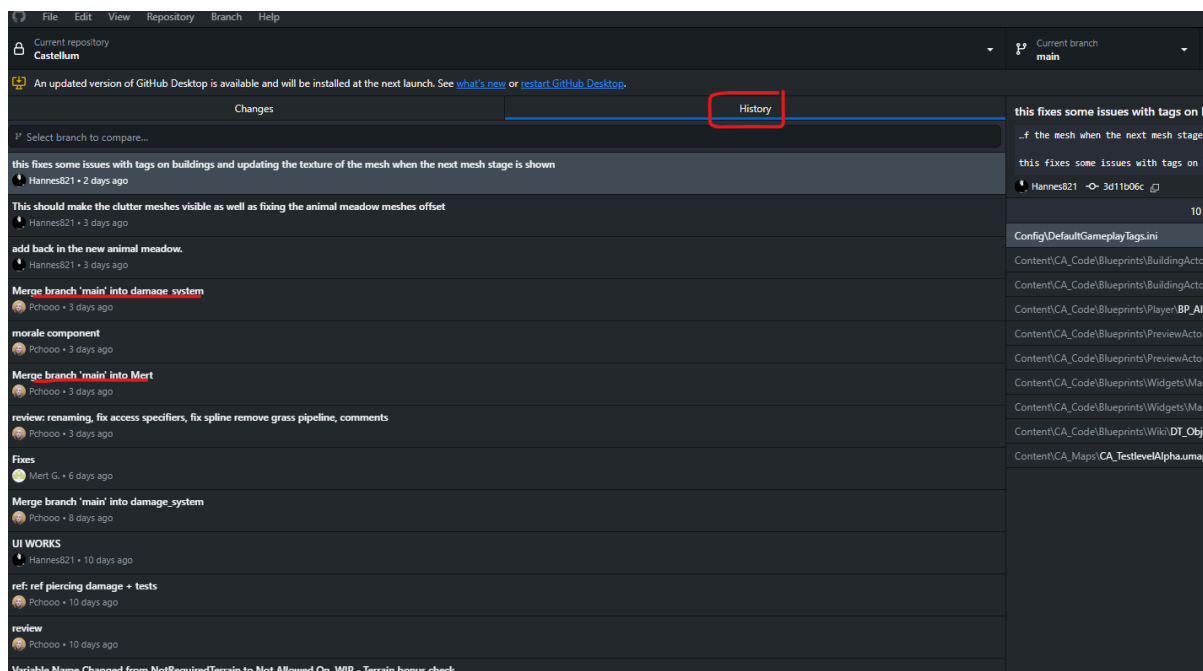

2. **Open, compile and test your changes for functionality. Close the editor.**

3. **Discard any dirty edits from your commit.**

4. **Add a proper description. Push the commit**

3. Some additional information

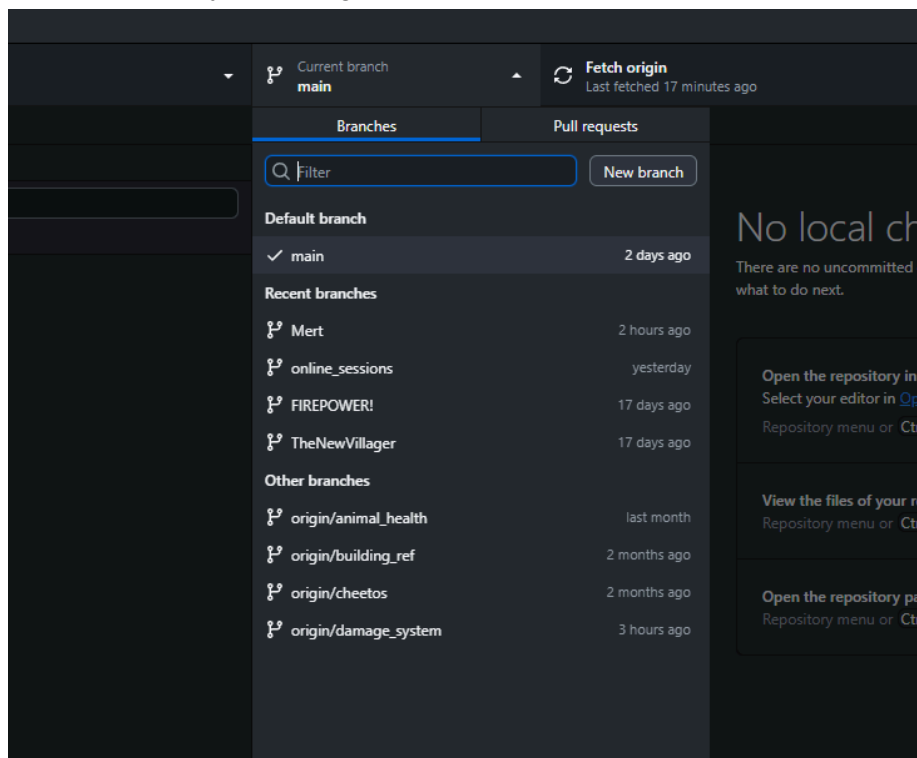

3.1 Checking History of a Branch

Check the history. You can see, if this branch was used to merge into other branches, see redlines.

3.2 Switching Branches:

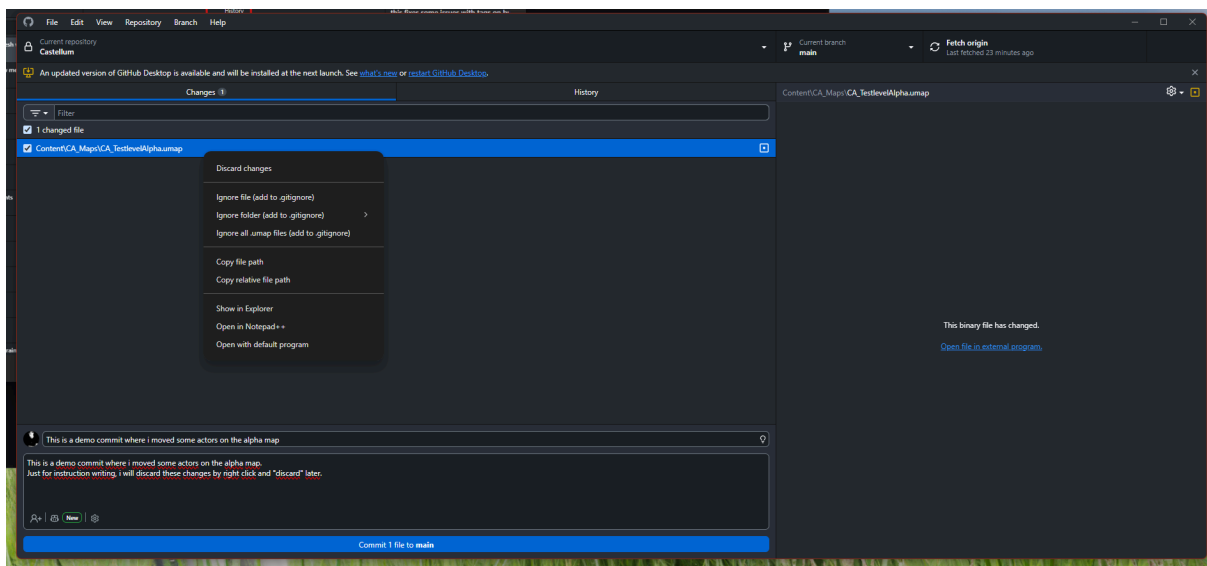

Changing your local copy to another version of what is online available.
Be sure to save your changes, stash them.

3.3 Fetching the latest Updates from the web

Always work with the latest version of branches to make sure you do not run into bad surprises, like suddenly overwriting on merge by a conflict you did not see! This could break the branch functionally.

3.4 Committing, Pushing

Your changes need to have a description and a headline, then you can “commit” and then you can “push” → send it to the online repository. Cleaning dirty edits means “discard” to unwanted changes.
